

# Gym Project – models.py Explanation

## What is models.py?

In this gym website project, models.py is used to define the database structure using Django ORM. Each model represents a database table and each field represents a column. Django handles all SQL operations internally.

## Workout Model

The Workout model is used to store gym workout information such as workout title, muscle group, videos, thumbnails, and description. The MUSCLE\_GROUP choice field ensures data consistency and avoids invalid inputs. FileField and ImageField are used to upload workout videos and thumbnails. The \_\_str\_\_ method improves readability in the Django admin panel.

## ContactMessage Model

This model stores messages submitted through the contact form. It includes the sender's name, message, and submission time. auto\_now\_add=True automatically saves the timestamp when the message is created.

## MemberModels

This model stores gym member registration details such as name, email, age, phone number, membership type, and join date. Choices are used to restrict membership types. PositiveIntegerField ensures age cannot be negative. Phone number is stored as CharField to support leading zeros.

## Key Django Concepts Used

- Django ORM (Object Relational Mapping)
- Python OOP and inheritance
- Choices for controlled inputs
- File handling and validation
- Database migrations and schema generation

## Interview Summary

The models are well-structured to separate workout content, contact messages, and member data. This design ensures scalability, maintainability, and clean data management.
